

Product Overview

The NSI1611S33 is a high-performance isolated amplifier with output separated from input based on NOVOSENSE capacitive isolation technology, which provides the amplifier with exceptional resistance to magnetic interference.

The device accepts a single-ended voltage input of 0.01-4V and provides a single-ended output which can help to reduce the external differential to single ended amplifier. The low offset and gain drift ensure the accuracy over the entire temperature range.

The NSI1611S33 features high input impedance, making it an ideal choice for applications where large resistive dividers are used or when connecting any high-impedance voltage signal source to the input.

The high common-mode transient immunity ensures that the device is able to provide accurate and reliable measurements even in the presence of high-power switching such as in motor control applications.

Key Features

- Up to 5700V_{rms} Insulation voltage
- 0.01~4V linear Input Voltage Range
- Single-Ended Output with Adjustable Gain:
 - Gain = 0.2* V_{REFIN}
 - V_{REFIN} = 3.0V recommended for best accuracy
- Low Offset Error and Drift:
 - ±1.5mV (Max), ±45μV/°C (Max)
- Low Gain Error and Drift:
 - ±0.25% (Max), ±35ppm/°C (Max)
- Low Nonlinearity and Drift:
 - ±0.04% (Max), ±1ppm/°C (Typ)
- SNR: 82dB (Typ, BW=10kHz), 71dB (Typ, BW=100kHz)
- Wide bandwidth: 330kHz (Typ)

- High CMTI: 150kV/μs (Typ)
- Operation Temperature: -40°C ~125°C
- RoHS-Compliant Packages: SOP8(300mil)

Safety Regulatory Approvals

- UL recognition: 5700V_{rms} for 1 minute per UL1577
- CQC certification per GB4943.1
- CSA component notice 5A
- DIN EN IEC 60747-17 (VDE 0884-17)

Applications

- Motor Drives
- Server Power Supply Units
- Energy Storage Systems
- Solar Inverters
- Charging Piles

1. Pin Configuration and Functions

Figure 1.1 NSI1611S33 Package(Not to scale)

Table 1.1 NSI1611S33 Pin Configuration and Description

NSI1611S33 PIN NO.	SYMBOL	FUNCTION
1	VDD1	Input side power supply
2	VIN	Single ended analog input
3	NC	Not internally connected, connecting to GND1 recommended
4	GND1	Input side ground
5	GND2	Output side ground
6	REFIN	Reference voltage input, connect to recommended voltage for best accuracy
7	OUT	Single-ended analog output
8	VDD2	Output side power supply

2. Absolute Maximum Ratings⁽¹⁾

Parameters	Symbol	Min	Typ	Max	Unit
Power Supply Voltage	VDDx to GNDx	-0.3		6.5	V
Analog Input Voltage	V _{IN}	GND-0.5		VDD1+0.5	V
Analog Output Voltage	OUT	GND-0.5		VDD2+0.5	V
Reference Input Voltage	REFIN	GND-0.5		VDD2+0.5	V
Input current per IO Pin	I _{IN}	-10		10	mA
Junction Temperature	T _J	-40		150	°C
Storage Temperature	T _{STG}	-55		150	°C

(1) The device cannot operate beyond the listed Absolute Maximum Ratings to prevent permanent device damage. The device is not fully functional if operating outside the Recommended Operating Conditions but within the Absolute Maximum Ratings. Long-time stress of the absolute maximum conditions may affect the device lifetime.

3. ESD Ratings

Parameters	Test Condition	Value	Unit
Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2.0	kV
	Charged device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±1.0	kV

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

4. Recommended Operating Conditions

Parameters	Symbol	Min	Typ	Max	Unit
Power supply voltage	VDD1 to GND1	4.5	5.0	5.5	V
	VDD2 to GND2 ⁽¹⁾	3.0	3.3	5.5	V
Input voltage before clipping output	V _{Clipping}		4.3		V
Linear differential input full scale voltage	V _{FSR}	0.01		4	V
Operating ambient temperature	T _A	-40		125	°C
Reference input voltage	V _{REFIN} ⁽²⁾	3.0	3.3	5.5	V

(1) Voltage of VDD2 must be higher than that of REFIN to ensure sufficient headroom for VOUT to output the required voltage.

(2) V_{REFIN} = 3.3V for best accuracy performance, refer to section 6.1 for details.

5. Thermal Information

<i>Parameters</i>	<i>Symbol</i>	<i>SOP8(300mil)</i>	<i>Unit</i>
Junction-to-ambient thermal resistance	$R_{\theta JA}$	86	°C/W
Junction-to-case (top) thermal resistance	$R_{\theta JC(top)}$	28	°C/W
Junction-to-board thermal resistance	$R_{\theta JB}$	42	°C/W
Junction-to-top characterization parameter	Ψ_{JT}	4	°C/W
Junction-to-board characterization parameter	Ψ_{JB}	42	°C/W

6. Specifications

6.1. Electrical Characteristics of NSI1611S33

(Minimum and maximum specifications apply across the following conditions: VDD1 = 4.5 ~ 5.5V, VDD2 = 3.0 ~ 5.5V, INP = 0.01V to 4V, V_{REFIN} = 3.3V T_A = -40°C to 125°C. Unless otherwise noted, Typical values are measured at VDD1 = VDD2 = 5V, T_A = 25°C)

Parameters	Symbol	Min	Typ	Max	Unit	Comments
Power Supply

8. Function Description

8.1. Overview

The NSI1611S33 is a high-performance isolated amplifier with an input range of 0.01~4V and a single-ended output. The buffer at the input port ensures the input impedance is high enough for large resistive dividers input. Subsequently, the analog signal is modulated to a digital waveform to transfer through the isolation barrier. Both the modulator and the isolator drivers (designated as TX in the functional block diagram) are clocked by the inside oscillator. The isolator receiver (designated as RX in the functional block diagram) receives the modulated waveform and restores it to an analog form.

Figure 8.1 Function Block Diagram of NSI1611S33

8.2. Analog Input

There are two restrictions on the analog input signals VIN

- If the input voltage exceeds the range from GND1–0.5V to VDD1+0.5V, the input current must be limited to 10 mA because the device input electrostatic discharge (ESD) diodes turn on.
- The linearity and noise performance of the device are ensured only when the analog input voltage remains within the specified linear full-scale range (V_{FSR}). V_{FSR} is 0.01V to 4V for NSI1611S33, specified in Recommended Operating Conditions section.

8.3. Analog Output

The NSI1611S33 outputs a single-ended voltage relative to GND2. The voltage gain from input to output can be configured by the voltage on the pin REFIN. When REFIN is connected to an external reference voltage above 2.5V, the NSI1611S33 has a dynamic output voltage range proportional to the voltage of REFIN. The input to output curve is shown in Figure 8.2 and the output follows Equation 1

$$V_{OUT} = 0.2 \times V_{REFIN} \times V_{IN} \quad \text{Equation 1}$$

The NSI1611S33 is trimmed under the condition that the voltage of REFIN is a precise 3.3V. It is highly recommended that the customers utilize the NSI1611S33 under the same condition for optimal accuracy performance. When the pin REFIN is applied with 3.3V, the nominal gain of NSI1611S33 is 0.66V/V.

Figure 8.2 Input to Output Transfer Curve of the NSI1611S33

8.4. Accuracy Guaranteed Range and Output Voltage Swing

The accuracy of NSI1611S33 is not guaranteed when input voltage approaches zero volt, as the output buffer requires a minimum headroom above GND2. However, the device still retains the ability to provide an output close to zero volt, which is guaranteed by the parameter V_{swing} . As shown in Figure 8.3, all specs are tested and guaranteed from 0.01V to maximum input voltage. When input voltage is below 0.01V, the output voltage still follows input voltage while not all specs are covered in final test. The minimum voltage this device can output is tested and denoted as V_{swing} .

Figure 8.3 Output Curve near zero voltage (not to scale)

8.5. Device Operating States

The NSI1611S33 can operate in the following states:

- **Missing low-side power supply state:** This state is entered when the low-side supply (VDD2) drops below the $VDD2_{UV}$ threshold. In this state, the device is unresponsive, and the output (OUT) is in a high-impedance (Hi-Z) state.
- **Missing high-side power supply state:** When the low-side of the device (VDD2) is properly powered and within the recommended operating conditions, but the high-side power supply (VDD1) is below the $VDD1_{UV}$ threshold, the OUT pin is driven to GND2.
- **Analog input overrange state:** With both VDD1 and VDD2 operating within the recommended conditions, if the analog input voltage (V_{IN}) exceeds the maximum clipping voltage ($V_{clipping, MAX}$), the device outputs $V_{clipping}$ at the OUT pin.

- **Normal operating state:** When VDD1, VDD2, and V_{IN} all fall within their respective recommended operating ranges, the device enters normal operation, and the output delivers a voltage proportional to the input voltage and REFIN voltage.

OPERATING STATES	VDD1	VDD2	V _{IN}	DESCRIPTION
Missing low-side power supply state	No effect	$VDD2 < VDD2_{UV}$	No effect	The output (OUT) is in a high-impedance (Hi-Z) state.
Missing high-side power supply state	$VDD1 < VDD1_{UV}$	Valid ⁽¹⁾	No effect	The OUT pin is driven to GND2.
Analog input overrange state	Valid ⁽¹⁾	Valid ⁽¹⁾	$V_{IN} > V_{clipping}$	The device outputs the clipping voltage: $V_{clipping} * Gain$
Normal operating state	Valid ⁽¹⁾	Valid ⁽¹⁾	Valid ⁽¹⁾	The device outputs a voltage according to Equation(1)

(1) Valid denotes operation within the recommended operating conditions.

Figure 8.4 illustrates the operating states under different kinds of combination of power supply states.

Figure 8.4 Waveform of NSI1611S33 when power fails

9. Application Note

9.1. Typical Application Circuit

Figure 9.1 illustrates a typical application example of NSI1611S33. On the input side, the HV_BUS voltage is divided down to 0.01~4V level across the bottom resistor of a high-impedance resistive divider. VDD1 needs a power supply from 4.5V to 5.5V. A 0.1uF capacitor and a 10uF capacitor in parallel on VDDx are recommended to improve EOS and stability. On the output side, NSI1611S33 provides an output proportional to the HV_BUS voltage

Figure 9.1 Typical Application Diagram of NSI1611S33

9.2. High Voltage Dividing Resistor Selection

Two restrictions should be considered when choosing the proper value of the voltage-dividing resistors:

- The current through the resistor should be within its rated range. Using Ohm law to calculate the cross current ($I_{cross} = V_{max}/R_{total}$);
- The divided input voltage value should not exceed the linear input range of NSI1611S33, in which case the output may be clipped.

9.3. Accuracy Related Parameters

Parameters related to the accuracy performance are explained in this section, including V_{os} and its drift, E_G and its drift, Nonlinearity. Other immunity parameters that affect accuracy like PSRR are also included.

9.3.1. Input Offset V_{os} and Gain Error E_G

V_{os} and E_G are the most significant factors influencing accuracy. The ideal curve and actual curve are shown in Figure 9.2.

Figure 9.2 Vos and EG diagram

V_{OS} means the input offset voltage when input is 0.01V for NSI1611S. The tested output should be divided by nominal gain as V_{OS} is defined as the offset voltage referred to input (See Equation 2).

$$V_{OS} = \frac{V_O}{\text{Nominal Gain}} - 0.01V \quad \text{Equation 2}$$

where

- V_O is the output voltage tested when input is 0.01V for NSI1611S33.
- Nominal Gain is $0.2 * V_{REFIN}$
- Gain is the magnification of the amplifier, and the definition formula is shown in Equation 2. EG means the difference between actual and ideal slope. It should be noted that EG is tested across the whole input range to minimize test error (See Equation 4).

$$\text{Gain} = \frac{\Delta y}{\Delta x} = \frac{V_{O1} - V_{O2}}{V_{IN1} - V_{IN2}} \quad \text{Equation 3}$$

$$E_G = \frac{\text{Gain} - \text{Nominal Gain}}{\text{Nominal Gain}} \times 100\% \quad \text{Equation 4}$$

- where V_{IN1} and V_{IN2} are the lower and upper limit of the input FSR separately, V_{O1} and V_{O2} are the output voltage corresponding to V_{IN1} and V_{IN2} .

9.3.2. Input Offset Drift TCV_{OS} and Gain Error Thermal Drift TCE_G

Input offset drift TCV_{OS} means the drift of V_{OS} over the whole operating temperature range, which is calculated as Equation 5.

$$TCV_{OS} = \frac{V_{OS_{max}} - V_{OS_{min}}}{\text{TempRange}} \quad \text{Equation 5}$$

where

- $V_{OS_{max}}$ and $V_{OS_{min}}$ are the maximum and minimum offset voltage over the whole operating ambient temperature range.
- TempRange covers the whole operating temperature, from -40°C to 125°C .

Gain error thermal drift TCE_G is the drift of E_G over the whole operating temperature range, which is calculated as Equation 6.

$$TCE_G = \frac{E_{G_{max}} - E_{G_{min}}}{\text{TempRange}} \quad \text{Equation 6}$$

where $E_{G_{max}}$ and $E_{G_{min}}$ are the maximum and minimum Gain Error over the whole temperature.

Both TCV_{OS} and TCE_G should be multiplied by the direction of temperature drift.

9.3.3. Nonlinearity

Nonlinearity describes the deviation between the actual output and the ideal linear output. Calculate the peak-to-peak value of the error between the actual output and the fitting curve, and nonlinearity is expressed as the ratio of half of the peak-to-peak error to the full-scale range of the output voltage (See Equation 7).

$$\text{Nonlinearity} = \frac{\text{Error_pkpk}}{2 \times V_{\text{OFSR}}} \times 100\% \quad \text{Equation 7}$$

where

- Error_pkpk is the peak-to-peak value of the error between the actual output and the fitting curve.
- V_{OFSR} represents the full-scale range of the output voltage.

9.3.4. Power-Supply Rejection Ratio

Power-Supply Rejection Ratio (PSRR) describes the level of the output error (input inferred) which is affected by the variation of power supply. PSRR is defined in dB and calculated as Equation 8.

$$\text{PSRR} = 20 \times \log_{10} \left(\frac{V_{\text{O_var}}}{\text{Nominal Gain} \times V_{\text{DD_var}}} \right) \quad \text{Equation 8}$$

Where $V_{\text{O_var}}$ and $V_{\text{DD_var}}$ are respectively the variation value of the output voltage and the supply voltage.

9.3.5. Total Error Calculation

The total error is contributed by parameters discussed above. It is helpful to know the respective contribution of all different parameters when something is wrong about system current sensing. This section will introduce the calculation method of total error.

Parameters which mainly affect sensing accuracy are V_{os} , EG and Nonlinearity and their drift. PSRR is not a dominant factor in most cases. However, PSRR can be a concern when the power supply has high-frequency ripple, in which case a larger decoupling capacitor and a better layout are highly recommended (Refer to Section 9.4).

The error introduced by V_{os} and its drift can be calculated as:

$$\text{Error_Vos} = \frac{V_{\text{os_max}} + \text{TCV}_{\text{os}} \times \Delta T}{V_{\text{IN}}} \times 100\% \quad \text{Equation 9}$$

where

- $V_{\text{os_max}}$ is the maximum value of input offset voltage at 25°C.
- TCV_{os} is the maximum drift of input offset voltage over the whole working temperature.
- ΔT is the range of temperature variation.
- V_{IN} is the input voltage in the application.

The error introduced by E_{G} and TCE_{G} can be calculated as :

$$\text{Error_E}_G = E_{\text{G}} + \text{TCE}_{\text{G}} \times \Delta T \quad \text{Equation 10}$$

where

- E_{G} is the maximum value of Gain Error when the temperature is 25°C.
- TCE_{G} is the maximum drift of Gain Error over the whole temperature.
- The error introduced by Nonlinearity is $\text{Nonlinearity}_{\text{max}}$, the maximum value of Nonlinearity in the entire temperature range, - 40°C to 125°C.

The total error sensing error is expressed as:

$$\text{Total_Error} = \sqrt{\text{Error_Vos}^2 + \text{Error_E}_G^2 + \text{Nonlinearity}_{\text{max}}^2} \quad \text{Equation 11}$$

For example, consider an NSI1611S33 with the sensing input voltage of 0~4V and a - 40°C to 85°C temperature range. The total error calculation is shown in Table 9.1.

Table 9.1 Total Error Calculation of NSI1611S33 (-40°C to 85°C)

Error Component	Symbol	Equation	Error at Vin=0.4V	Error at Vin=4.0V
Input offset error	Error_Vos	$\text{Error_Vos} = \frac{V_{os_{max}} + TCV_{os} \times \Delta T}{V_{IN}} \times 100\%$ $= \frac{\pm 1.5\text{mV} \pm 45\mu\text{V}/^\circ\text{C} \times 60^\circ\text{C}}{V_{IN}} \times 100\%$	±1.05%	±0.105%
Gain error	Error_EG	$\text{Error_EG} = E_G + TCE_G \times \Delta T = \pm 0.25\% \pm 35\text{ppm}/^\circ\text{C} \times 60^\circ\text{C}$	±0.46%	±0.46%
Nonlinearity	Nonlinearity _{max}	$\text{Nonlinearity}_{max} = \pm 0.04\%$	±0.04%	±0.04%
Total error	Total_Error	$\text{Total_Error} = \sqrt{\text{Error_Vos}^2 + \text{Error_EG}^2 + \text{Nonlinearity}_{max}^2}$	±1.147%	±0.474%

Since the input offset voltage is independent of input voltage, it becomes the dominant factor of the total error when the input voltage is low. To improve the system accuracy, especially under low-input applications, it is recommended to perform software zero-point calibration and gain error calibration. With system-level calibration, the total error can also be reduced significantly. The reduced error is calculated as Table 9.2.

Table 9.2 Total Error Calculation with Software Calibration of NSI1611S33 (- 40°C to 85°C)

Error Component	Symbol	Equation	Error at Vin=0.4 V	Error at Vin=4.0V
Input offset error	Error_Vos	$\text{Error_Vos} = \frac{TCV_{os} \times \Delta T}{V_{IN}} \times 100\%$ $= \frac{\pm 45\mu\text{V}/^\circ\text{C} \times 60^\circ\text{C}}{V_{IN}} \times 100\%$	±0.675%	±0.0675%
Gain error	Error_EG	$\text{Error_EG} = TCE_G \times \Delta T = \pm 35\text{ppm}/^\circ\text{C} \times 60^\circ\text{C}$	±0.21%	±0.21%
Nonlinearity	Nonlinearity _{max}	$\text{Nonlinearity}_{max} = \pm 0.04\%$	±0.04%	±0.04%
Total error	Error	$\text{Total_Error} = \sqrt{\text{Error_Vos}^2 + \text{Error_EG}^2 + \text{Nonlinearity}_{max}^2}$	±0.708%	±0.224%

The maximum total error with and without calibration is shown in Figure 9.3, considering 0~4V input as full input range, NSI1611S33 can achieve <0.75% error at more than 10% input voltage (Vin≥0.4V) with software calibration, and <1.2% error at more than 10% load (Vin≥0.4V) without software calibration.

9.4. PCB Layout

Figure 9.4 shows a typical layout example of NSI1611S33. To enhance power supply noise immunity and EOS robustness, it is recommended to use a low-ESR 100nF capacitor (C2, C4) in parallel with a low-ESR 1 μ F capacitor (C1, C3). These capacitors should be positioned as close as possible to the power supply pins, and the smaller-value capacitors should be in the inner place as they usually have a lower ESR and better immunity to high-frequency interference.

An additional capacitor(C5) is recommended to be added in parallel with lower side divided resistor(R3). The capacitor is also recommended to be positioned as close as possible to the input pin VIN.

An input RC filter (R5 and C7) is recommended to be added to the REFIN pin. The passband of internal input filter is about 100kHz, a lower bandwidth may provide better result in case of interference.
